Introduction to Data Assimilation

Based on a presentation of Alan O’Neill
Data Assimilation Research Centre
University of Reading

Outline

• Motivation
• Univariate (scalar) data assimilation
  – Optimal Interpolation (BLUE)
  – 3D-Variational Method
  – Kalman Filter
  – 4D-Variational Method
• Applications to earth system science

Motivation

What is data assimilation?

Data assimilation is the technique whereby observational data are combined with output from a numerical model to produce an optimal estimate of the evolving state of the system.

Why We Need Data Assimilation

• range of observations
• range of techniques
• different errors
• data gaps
• quantities not measured
• quantities linked

Current & Future Satellite Coverage
Chemical analysis

O₃ measured by MIPAS/Envisat

Assimilation of O₃ data into GCM

2020 VISION

• By 2020 the Earth will be viewed from space with better than 1km/1min resolution
• Computer power will be ~1000 times greater than it is today
• To exploit this technological revolution, the world must be digitised

Welcome to Music World

What experts get
10 soundtracks
High-tech Sampler
Synthesis of tracks
What end-users want
Well-balanced high-quality blended music
Vital to ensure Return On Investment!

Welcome to Digi World

What users get
Level 2 for individual sensor
High-tech Sampler
Synthesis via Assimilation of EO data into Earth System Model
What end-users want
4D digital movie of the Earth System
Weather forecasting

Satellite data have contributed to the continuous improvement of forecast quality with enormous benefits for society.

Numerical Weather Prediction:
- Sophisticated atmospheric models.
- Most mature assimilation techniques (able to ingest sounding radiances).
- Very big user of EO data.

Some Uses of Data Assimilation

- Operational weather forecasting
- Ocean forecasting
- Seasonal weather forecasting
- Land-surface process
- Global climate datasets
- Planning satellite measurements
- Evaluation of models and observations

What We Want To Know

\[ x(t) \text{ atmos. state vector} \]
\[ s(t) \text{ surface fluxes} \]
\[ c \text{ model parameters} \]
\[ X(t) = (x(t), s(t), c) \]
What We Also Want To Know

Errors in models
Errors in observations
What observations to make

The Data Assimilation Process

observations forecasts
compare reject adjust
estimates of state & parameters errors in obs. & forecasts

Data Assimilation: an analogy

Driving with your eyes closed:
Open your eyes every 10 seconds and correct your trajectory !!!
Basic Concept of Data Assimilation

• Information is accumulated in time into the model state and propagated to all variables.

What are the benefits of data assimilation?

• Quality control
• Combination of data
• Errors in data and in model
• Filling in data poor regions
• Designing observational systems
• Maintaining consistency
• Estimating unobserved quantities

Methods of Data Assimilation

• Optimal interpolation (or approx. to it)
• 3D variational method (3DVar)
• 4D variational method (4DVar)
• Kalman filter (with approximations)

Types of Data Assimilation

• Intermittent
• Continuous

Intermittent Assimilation

Continuous Assimilation
Data Assimilation Made Simple (scalar case)

Least Squares Method (Minimum Variance)

\[
\begin{align*}
\bar{T}_1 &= \bar{T}_1 + \epsilon_1 \\
\bar{T}_2 &= \bar{T}_2 + \epsilon_2 \\
\langle \epsilon_1 \rangle &= 0 \\
\langle \epsilon_2 \rangle &= 0 \\
\langle \epsilon_1 \rangle^2 &= \sigma_1^2 \\
\langle \epsilon_2 \rangle^2 &= \sigma_2^2 \\
\langle \epsilon_1 \epsilon_2 \rangle &= 0, \text{the two measurements are uncorrelated} \\
\text{Estimate } \bar{T}_n \text{ as a linear combination of the observations} \\
\bar{T}_n &= a_1 \bar{T}_1 + a_2 \bar{T}_2 \\
\text{The analysis should be unbiased: } \langle \bar{T}_n \rangle &= \langle \bar{T}_1 \rangle \\
\Rightarrow a_1 + a_2 &= 1
\end{align*}
\]

Least Squares Method Continued

Estimate \( \bar{T}_n \) by minimizing its mean squared error:

\[
\begin{align*}
\sigma_n^2 &= \langle (\bar{T}_n - \bar{T}_1)^2 \rangle \\
&= \langle (a_1(\bar{T}_1 - T_1) + a_2(\bar{T}_2 - T_2))^2 \rangle \\
&= \langle (a_1 \epsilon_1 + a_2 \epsilon_2)^2 \rangle \\
&= a_1^2 \sigma_1^2 + a_2^2 \sigma_2^2
\end{align*}
\]

subject to the constraint \( a_1 + a_2 = 1 \)

Least Squares Method Continued

\[
\begin{align*}
a_1 &= \frac{1}{\sigma_1^2 + \frac{1}{\sigma_2^2}} \\
a_2 &= \frac{1}{\sigma_2^2 + \frac{1}{\sigma_1^2}}
\end{align*}
\]

The precision of the analysis is the sum of the precisions of the measurements. The analysis therefore has higher precision than any single measurement.
**Variational Approach**

\[ J(T) = \frac{1}{2} \left( \frac{(T - T_0)^2}{\sigma_x^2} + \frac{(T - T_i)^2}{\sigma_i^2} \right) \]

\( T_o \) is the value of \( T \) for which \( \frac{\partial J}{\partial T} = 0 \)

**Simple Sequential Assimilation**

Let \( T_i = T_0 \) \( T = T_n \)

\( T_s = T_i + W(T_n - T_i) \) where \( (T_s - T_i) \) is the "innovation".

The optimal weight \( W \) is given by:

\( W = \sigma_x^2 / (\sigma_x^2 + \sigma_i^2) \)

and the analysis error variance is:

\( \sigma_s^2 = (1 - W) \sigma_x^2 \)

**Comments**

- The analysis is obtained by adding first guess to the innovation.
- Optimal weight is background error variance multiplied by inverse of total variance.
- Precision of analysis is sum of precisions of background and observation.
- Error variance of analysis is error variance of background reduced by \( (1 - \text{optimal weight}) \).

**Simple Assimilation Cycle**

- Observation used once and then discarded.
- Forecast phase to update \( T_0 \) and \( \sigma_b^2 \)
- Analysis phase to update \( T_s \) and \( \sigma_s^2 \)
- Obtain background as

\( T_b(t_i) = M[T_s(t_i)] \)

- Obtain variance of background as

\( \sigma_b^2(t_i) = \sigma_s^2(t_i) \) alternatively \( \sigma_b^2(t_i) = a \sigma_s^2(t_i) \)

**Multivariate Case**

State vector \( x(t) = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} \)

Observation vector \( y(t) = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_m \end{pmatrix} \)
State Vectors

\( \mathbf{X} \)  
state vector (column matrix)

\( \mathbf{X}_t \)  
true state

\( \mathbf{X}_b \)  
background state

\( \mathbf{X}_a \)  
analysis, estimate of \( \mathbf{X}_t \)

Ingredients of Good Estimate of the State Vector ("analysis")

- Start from a good “first guess” (forecast from previous good analysis)
- Allow for errors in observations and first guess (give most weight to data you trust)
- Analysis should be smooth
- Analysis should respect known physical laws

Some Useful Matrix Properties

Transpose of a product: \((\mathbf{AB})^T = \mathbf{B}^T \mathbf{A}^T\)

Inverse of a product: \((\mathbf{AB})^{-1} = \mathbf{B}^{-1} \mathbf{A}^{-1}\)

Inverse of a transpose: \((\mathbf{A}^T)^{-1} = (\mathbf{A}^{-1})^T\)

Positive definiteness for symmetrix matrix \( \mathbf{A} \):
\( \forall \ \mathbf{x}, \text{the scalar } \mathbf{x} \mathbf{A} \mathbf{x}^T > 0, \text{ unless } \mathbf{x} = \mathbf{0}. \)
(this property is conserved through inversion)

Observations

- Observations are gathered into an observation vector \( \mathbf{Y} \), called the observation vector.
- Usually fewer observations than variables in the model; they are irregularly spaced; and may be of a different kind to those in the model.
- Introduce an observation operator to map from model state space to observation space.

\[ \mathbf{x} \rightarrow \mathbf{H}(\mathbf{x}) \]

Errors

Variance becomes Covariance Matrix

- Errors in \( x_i \) are often correlated
  - spatial structure in flow
  - dynamical or chemical relationships
- Variance for scalar case becomes Covariance Matrix for vector case \( \mathbf{COV} \)
- Diagonal elements are the variances of \( x_i \)
- Off-diagonal elements are covariances between \( x_i \) and \( x_j \)
- Observation of \( x_i \) affects estimate of \( x_j \)
The Error Covariance Matrix
\[
\mathbf{P} = \mathbf{E^T E} = \begin{pmatrix}
\langle e_1 e_1 \rangle & \langle e_1 e_2 \rangle & \ldots & \langle e_1 e_n \rangle \\
\langle e_2 e_1 \rangle & \langle e_2 e_2 \rangle & \ldots & \langle e_2 e_n \rangle \\
\vdots & \vdots & \ddots & \vdots \\
\langle e_n e_1 \rangle & \langle e_n e_2 \rangle & \ldots & \langle e_n e_n \rangle \\
\end{pmatrix}
\]

Background Errors
- They are the estimation errors of the background state:
  \[\mathbf{E_b} = \mathbf{X_b} - \mathbf{X_t}\]
- average (bias) \[\langle \mathbf{E_b} \rangle\]
- covariance \[\mathbf{B} = \langle (\mathbf{E} - \langle \mathbf{E_b} \rangle)(\mathbf{E} - \langle \mathbf{E_b} \rangle)^T \rangle\]

Observation Errors
- They contain errors in the observation process (instrumental error), errors in the design of \(H\), and "representativeness errors", i.e. discretization errors that prevent \(\mathbf{X_b}\) from being a perfect representation of the true state.
  \[\mathbf{E_o} = \mathbf{y} - H(\mathbf{x}_t) < \mathbf{E_o} >\]
  \[\mathbf{R} = \langle (\mathbf{E_o} - < \mathbf{E_o} >)(\mathbf{E_o} - < \mathbf{E_o} >)^T \rangle\]

Control Variables
- We may not be able to solve the analysis problem for all components of the model state (e.g. cloud-related variables, or need to reduce resolution)
- The work space is then not the model space but the sub-space in which we correct \(\mathbf{X_b}\), called control-variable space
  \[\mathbf{X_a} = \mathbf{X_b} + \hat{\Delta}\mathbf{X}\]

Innovations and Residuals
- Key to data assimilation is the use of differences between observations and the state vector of the system
- We call \(\mathbf{y} - H(\mathbf{x}_b)\) the innovation
- We call \(\mathbf{y} - H(\mathbf{x}_a)\) the analysis residual

Analysis Errors
- They are the estimation errors of the analysis state that we want to minimize.
  \[\mathbf{E_a} = \mathbf{X_a} - \mathbf{X_t}\]
  Covariance matrix \(\mathbf{A}\)
Using the Error Covariance Matrix
Recall that an error covariance matrix \( \mathbf{C} \) for the error in \( \mathbf{x} \) has the form:
\[
\mathbf{C} = \mathbf{E} \mathbf{E}^T
\]
If \( \mathbf{y} = \mathbf{Hx} \) where \( \mathbf{H} \) is a matrix, then the error covariance for \( \mathbf{y} \) is given by:
\[
\mathbf{C}_y = \mathbf{HCH}^T
\]

BLUE Estimator
• The BLUE estimator is given by:
\[
\mathbf{x}_a = \mathbf{x}_b + \mathbf{K}(\mathbf{y} - \mathbf{H}(\mathbf{x}_b))
\]
\[
\mathbf{K} = \mathbf{BH}^T(\mathbf{HBH}^T + \mathbf{R})^{-1}
\]
• The analysis error covariance matrix is:
\[
\mathbf{A} = (\mathbf{I} - \mathbf{KH})\mathbf{B}
\]
• Note that:
\[
\mathbf{BH}^T(\mathbf{HBH}^T + \mathbf{R})^{-1} = (\mathbf{B}^{-1} + \mathbf{H}^T\mathbf{R}^{-1}\mathbf{H})^{-1}\mathbf{H}^T\mathbf{R}^{-1}
\]

Statistical Interpolation with Least Squares Estimation
• Called Best Linear Unbiased Estimator (BLUE).
• Simplified versions of this algorithm yield the most common algorithms used today in meteorology and oceanography.

Assumptions Used in BLUE
• Linearized observation operator:
\[
\mathbf{H}(\mathbf{x}) - \mathbf{H}(\mathbf{x}_b) = \mathbf{H}(\mathbf{x} - \mathbf{x}_b)
\]
• \( \mathbf{B} \) and \( \mathbf{R} \) are positive definite.
• Errors are unbiased:
\[
\mathbf{x}_b - \mathbf{x}_t = \mathbf{y} - \mathbf{H}(\mathbf{x}_t) = 0
\]
• Errors are uncorrelated:
\[
\mathbf{x}_b - \mathbf{x}_t \mathbf{(y} - \mathbf{H}(\mathbf{x}_t))^T = 0
\]
• Linear analysis: corrections to background depend linearly on (background – obs.).
• Optimal analysis: minimum variance estimate.

Optimal Interpolation
\[
\mathbf{x}_a = \mathbf{x}_b + \mathbf{K}(\mathbf{y} - \mathbf{H}(\mathbf{x}_b))
\]
• linearity \( \mathbf{H} \rightarrow \mathbf{H} \)
• matrix inverse
• limited area

\[
\mathbf{K} = \mathbf{BH}^T(\mathbf{HBH}^T + \mathbf{R})^{-1}
\]

\[\Delta = \mathbf{y} - \mathbf{H}(\mathbf{x}_b)\quad \text{at obs. point}\]
Spreading of Information from Single Pressure Obs.

MIPAS observations

6 day model forecast

Ozone at 10hPa, 12Z 23rd Sept 2002

Analysis

3D variational data assimilation - ozone at 10hPa

The data assimilation cycle: ozone at 10hPa
Estimating Error Statistics

- Error variances reflect our uncertainty in the observations or background.
- Often assume they are stationary in time and uniform over a region of space.
- Can estimate by observational method or as forecast differences (NMC method).
- More advanced, flow dependent errors estimated by Kalman filter.

Estimating Covariance Matrix for Observations, $R$

- $R$ is usually quite simple:
  - Diagonal,
  - or, for nadir-sounding satellites,
  - Non-zero values between points in vertical only
- Calibration against independent measurements

Estimating the Error Covariance Matrix $B$

- Model $B$ with simple functions based on comparisons of forecasts with observations:
  $$B = \sigma_x \sigma_y \exp(-d^2/\hat{L})$$
- Error growth in short-range forecasts “verifying” at the same time (NMC method)
  $$B \approx \langle[x_j(48h) - x_j(24h)][x_j(48h) - x_j(24h)]^T \rangle$$
  state vector at time $t$ from forecast 48h or 24h earlier

3d-Variational Data Assimilation

Variational Data Assimilation

- BLUE analysis can be obtained by minimizing a cost (penalty, performance) function:
  $$J(x) = (x - x_o)^T B^{-1} (x - x_o) + (y - H(x))^T R^{-1} (y - H(x))$$
  $$J(x) = J_b(x) + J_o(x)$$
  $$x_a = \min J$$
- The analysis $x_a$ is optimal (closest in least-squares sense to $x_o$).
- If the background and observation errors are Gaussian, then $x_a$ is also the maximum likelihood estimator.
Remarks on 3D-VAR

- Can add constraints to the cost function, e.g. to help maintain “balance”
- Can work with non-linear observation operator $H$.
- Can assimilate radiances directly (simpler observational errors).
- Can perform global analysis instead of OI approach of radius of influence.

Variational Data Assimilation

$$J(x) = (x - x_b)^T B^{-1} (x - x_b) + (y - H(x))^T R^{-1} (y - H(x))$$

**nonlinear operator**

**assimilate y directly**

**global analysis**

Effect of Observed Variables on Unobserved Variables

- Implicitly through the governing equations of the (forecast) model.
- Explicitly through the off-diagonal terms in $B$:

$$\begin{bmatrix} a & c \\ c & b \end{bmatrix} \begin{bmatrix} y_1 - H(x_1) \\ y_2 - H(x_2) \end{bmatrix} = \begin{bmatrix} a & c \\ c & b \end{bmatrix} \begin{bmatrix} x_1 - x_b \\ x_2 - x_b \end{bmatrix}$$

(assume that $y_1$ is a measurement of $x_1$, but $y_2$ not measured)

Choice of State Variables and Preconditioning

- Free to choose which variables to use to define state vector, $x(t)$
- We’d like to make $B$ diagonal
  - may not know covariances very well
  - want to make the minimization of $J$ more efficient by “preconditioning”: transforming variables to make surfaces of constant $J$ nearly spherical in state space

Cost Function for Correlated Errors

Cost Function for Uncorrelated Errors
14

Cost Function for Uncorrelated Errors
Scaled Variables

4D-Variational Assimilation

4D Variational Data Assimilation

given $X(t_0)$, the forecast is deterministic

vary $X(t_0)$ for best fit to data

4D-VAR For Single Observation
at time $t$

$J(x(x_0, t))$

where $H(\tilde{x}) = y$

4D-Variational Assimilation

$$J(x(t_0)) = \frac{1}{2} \sum_{j=0}^{N} [y_j - H(x_j)]^T R_j^{-1} [y_j - H(x_j)] + \frac{1}{2} [x(t_0) - x^t(t_0)]^T B_0^{-1} [x(t_0) - x^t(t_0)]$$

where $x(t) = M_{0\to t}(x(t_0))$ i.e. the model is treated as a strong constraint

Minimize the cost function by finding the gradient $\frac{\partial J}{\partial x(t_0)}$ ("Jacobian") with respect to the control variables in $x(t_0)$

4D-VAR Continued

The 2nd term on the RHS of the cost function measures the distance to the background at the beginning of the interval. The term helps join up the sequence of optimal trajectories found by minimizing the cost function for the observations. The "analysis" is then the optimal trajectory in state space. Forecasts can be run from any point on the trajectory, e.g. from the middle.
Some Matrix Algebra

\[ J = J(x(x_0)) \]

adjoint of the model

\[ M = x_0 \alpha \]

Then

\[ \frac{\partial J}{\partial x_0} = \left( \frac{\partial M}{\partial x_0} \right)^T \frac{\partial J}{\partial x} \]

Let \( J \) have the following form:

\[ J = x^T (x) \alpha x \]

Then it can be shown that

\[ \frac{\partial J}{\partial x_0} = \left( \frac{\partial x}{\partial x_0} \right)^T \alpha x \]

Combining these results:

\[ \frac{\partial J}{\partial x_0} = \left( \frac{\partial x}{\partial x_0} \right)^T \left( \frac{\partial x}{\partial x_0} \right)^T \alpha x \]

4D-VAR for Single Observation

\[ J(x(x_0)) = \frac{1}{2} [y - H(x(x_0))]^T R^{-1} [y - H(x(x_0))] \]

By using results on slide "Some Matrix Algebra":

\[ \frac{\partial J}{\partial x_0} = -L_{0,0}^T H^T R^{-1} [y - H(x(x_0))] = -L_{0,0}^T d \]

where

\[ L_{0,0}^T = \left( \frac{\partial x}{\partial x_0} \right)^T = \frac{\partial M^T(x_0)}{\partial x_0} \]

This is the adjoint of the tangent linear model

\[ L_{0,0}^T = L_{0,0}^T \cdots L_{i_{1}=i_{2}} \cdots d \]

4D-VAR Procedure

- Choose \( x_0, x_0^b \) for example.
- Integrate full (non-linear) model forward in time and calculate \( d \) for each observation.
- Map \( d \) back to \( t=0 \) by backward integration of TLM, and sum for all observations to give the gradient of the cost function.
- Move down the gradient to obtain a better initial state (new trajectory "hits" observations more closely)
- Repeat until some STOP criterion is met.

**note:** not the most efficient algorithm

Comments

- 4D-VAR can also be formulated by the method of Lagrange multipliers to treat the model equations as a constraint. The adjoint equations that arise in this approach are the same equations we have derived by using the chain rule of partial differential equations.
- If model is perfect and \( B_0 \) is correct, 4D-VAR at final time gives same result as extended Kalman filter (but the covariance of the analysis is not available in 4D-VAR).
- 4D-VAR analysis therefore optimal over its time window, but less expensive than Kalman filter.

Incremental Form of 4D-VAR

- The 4d-VAR algorithm presented earlier is expensive to implement. It requires repeated forward integrations with the non-linear (forecast) model and backward integrations with the TLM.
- When the initial background (first-guess) state and resulting trajectory are accurate, an incremental method can be made much cheaper to run on a computer.

Incremental Form of 4D-VAR

The incremental form of the cost function is defined by

\[ J(\delta x_i) = \frac{1}{2} (\delta x_i)^T B_0^{-1} (\delta x_i) + \frac{1}{2} \sum_{i=1}^{n} \left( y_i - H(x(t_i)) - H(x(t_i)) \delta x_i \right)^T \left( y_i - H(x(t_i)) - H(x(t_i)) \delta x_i \right) \]

Taylor series expansion about first-guess trajectory \( x_i(t_i) \)

Minimization can be done in lower dimensional space
4D Variational Data Assimilation

• Advantages
  – consistent with the governing eqs.
  – implicit links between variables

• Disadvantages
  – very expensive
  – model is strong constraint
